

P5 — Protocol-driven (cryoscope) vs analytic transfer-function measurement

(a) Cryoscope vs analytic, true $A=0.05$, $\tau=100$ ns

(b) The residual is a PROTOCOL ARTIFACT, not noise: an undistorted line shows the same structure

(c) Operating range: window validity (bars) and step-amplitude artifact (inset)

(d) Two orthogonal error sources: rmse is flat (artifact-dominated), recoverability tracks the surviving tail
