

Transfer-function fit quality and model-order selection (sqc)

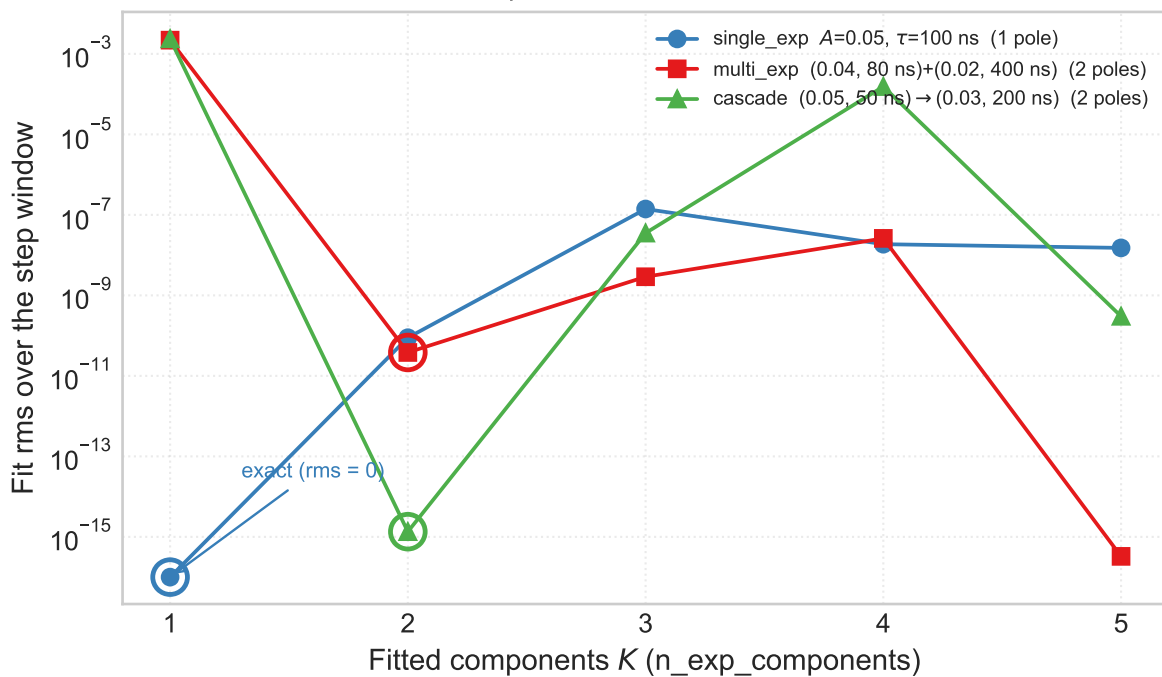

(a) Measured vs fitted step, 2-pole truth
K=1 underfits; K=2 lands on the data

(b) Fit residual (log-y): the underfit floor is
8 orders above the correct order

(c) Model-order selection (circled = true pole count)
rms collapses at $K = K_{true}$, then scatters

(d) Parameter recovery at $K = K_{true}$
solid = amplitude, hatched = τ
